Is Posner Schlossman Syndrome Benign?

Aliza Jap, FRCS (G),¹ Meenakshi Sivakumar, FRCS (Ed), M Med (Ophth),²,† Soon-Phaik Chee, FRCS (Ed), FRCOphth²

Purpose: To determine the clinical course of patients with Posner Schlossman syndrome (PSS).

Design: Retrospective noncomparative case series.

Participants: Fifty-three eyes of 50 patients.

Methods: The case notes of all patients with PSS seen at the Uveitis Clinic of Singapore National Eye Centre were reviewed for evidence of glaucoma damage and risk factors.

Main Outcome Measures: Visual field and optic disc changes consistent with glaucoma.

Results: There were 28 men and 22 women, and their mean age at onset was 35 years. Fourteen eyes (26.4%) were diagnosed to have developed glaucoma as a result of repeated attacks of PSS. Patients with 10 years or more of PSS have a 2.8 times higher risk (95% confidence interval 1.19–6.52) of developing glaucoma compared with patients with less than 10 years duration of the disease. Nine eyes (17%) underwent glaucoma filtering surgery with antimetabolites. Their postoperative follow-up ranged from 15 to 50 months (mean, 37 months). Four eyes continued to have episodes of iritis after surgery, and one of these eyes had elevated intraocular pressure during the event.

Conclusions: A significant number of patients with PSS have glaucoma develop over time, and they need to have their optic disc appearance and visual fields carefully monitored. Ophthalmology 2001;108:913–918 © 2001 by the American Academy of Ophthalmology.
2. The unaffected eye had normal IOP, optic discs and fields
3. The affected eye had glaucomatous optic disc and/or visual fields

All patients had at least one visual field performed on the Humphrey Field Analyzer (Humphrey Instruments, Inc, San Leandro, CA) using the 24-2 or 30-2 program. The criteria, in a reliable reproducible field with less than 15% false-negative and less than 15% false-positive responses, used for the diagnosis of glaucoma were5:

- A cluster of two or more central points depressed by 5 or more decibels
- A single point depressed by 10 or more decibels
- A difference of 5 or more decibels across the nasal horizontal meridian at two or more contiguous points

Optic disc criteria for glaucoma included6–9:

- Cup/disc ratio greater than 0.7
- Notching of neuroretinal rim or focal pit
- Narrowest remaining neuroretinal rim of 0.1 disc diameter or less
- Asymmetry in cup/disc ratio of more than 0.2
- Progressive thinning of the neuroretinal rim
- Increase in cup/disc ratio

The first four criteria are not in themselves diagnostic of glaucoma, and eyes with these changes were graded as having glaucoma only if they had concomitant field changes.

The field and disc photographs were assessed by one of the authors according to the criteria listed, and only those that had obvious changes were classified as having glaucoma damage. Not all the patients had good sequential stereoscopic disc photographs, and disc changes were given relatively low priority in the assessment.

Results

There were 53 eyes of 50 patients, with three of the patients having bilateral attacks, and these eyes were analyzed separately. Their mean age at onset was 35 years (range, 17–61 years). Twenty-two of the patients were women and 28 men. Most were Chinese (n = 45), with 4 Malays, and 1 Indian. Only three patients had diabetes mellitus. The mean duration of their disease was 7 years (range, 1–24 years). All had at least three documented attacks of PSS. None of eyes required or received any steroids or antiglaucoma therapy in between attacks.

Fourteen eyes (26.4%) had glaucomatous damage develop because of repeated attacks of PSS. Two of these eyes belonged to the same patient.

Eleven of the eyes had normal discs and fields initially, but over a mean follow-up period of 10 years (range, 2–20 years) they were observed to have glaucomatous damage develop. Ten of these eyes had both disc and field changes. In the eleventh eye, there was an increase in the cup/disc ratio from 0.3 to 0.5, with no field changes, whereas in the normal fellow eye, the cup/disc ratio remained at 0.2 throughout the period of follow-up.

Three of the eyes already had significant field and disc changes by the time that they presented to an ophthalmologist (Table 2). The age of onset, highest IOP, duration of the disease, and number of attacks among the patients who had glaucoma develop and those who did not were compared by use of Student’s t test.

*Initial C/D = cup/disc ratio at diagnosis.

†Last C/D ratio = cup/disc ratio at last visit.

5FUTrab = trabeculectomy with intraoperative application of 50 mg/ml 5-fluorouracil.

MMCTrab = trabeculectomy with intraoperative application of 0.3 mg/ml mitomycin-C.
The only factor, that was predictive of the development of glaucoma was the duration of the disease (Table 3). The risk of glaucoma developing after 10 or more years of exposure is 2.8 times higher (95% confidence interval, 1.19–6.52) than in those with less than 10 years of the disease.

Nine of the eyes (17%) had progressive damage and underwent glaucoma filtering surgery. One eye received a trabeculectomy with mitomycin-C and the other eight received a trabeculectomy with intraoperative application of 5-fluorouracil (50 mg/ml applied for 5 minutes). Their mean postoperative follow-up was 37 months (range, 15–50 months). Their mean IOP at the last visit was 10 mmHg (range, 6–15 mmHg). One of the eyes required two anti-glaucoma drops; the rest of the eyes were on no medications.

In the year before surgery, these nine eyes had three to four attacks of iritis each, but in the year after surgery, six eyes had no further attacks of iritis. In the three eyes that continued to have episodes of iritis after surgery, two eyes had one attack each with no elevation of IOP during the attack and one eye had 15 attacks with elevated IOP during the attacks. This has resulted in failure of the initially functioning bleb with progression of the glaucoma damage. The other eight eyes had avascular functioning blebs at the last visit, and there has been no further glaucomatous damage in these eyes.

Fifty of the eyes had 6/9 or better vision at the last visit, two eyes had 6/12 vision because of cataract, and one eye had lost light perception because of progression of his glaucoma.

**Case Reports**

**Patient 12—Right and Left Eyes**

This Chinese man was first seen in 1979 at the age of 30 with evidence of PSS in both eyes. He continued to have nonsimultaneous acute attacks about once a year. The highest IOP in his right eye was 36 mmHg and in his left eye was 40 mmHg. In 1994 his cup/disc ratio was noted to be 0.8 in the right eye and 0.6 in the left eye. Visual field testing at that time showed severe superior arcuate and inferior nasal loss in the right eye and a small nasal step in the left eye (Fig 1A,B). He received a right trabeculectomy with 5-fluorouracil in January 1995, and the field in the right eye has remained stable since then.

In the meantime, he continued to have repeated attacks of cyclitis, accompanied by IOP spikes in the left eye, and he underwent trabeculectomy with 5-fluorouracil in March 1995 in that eye. The visual field of the left eye in January 1996 showed extensive superior and inferior arcuate loss. Because his IOPs had remained between 8 and 10 mmHg during this time, the damage presumably occurred as a result of the preoperative episodes of cyclitis. The visual field in March 1998, 5 months after cataract surgery, showed essentially the same pattern of loss (Fig 1C–E). Postoperatively, his IOP ranged from 7 to 14 mmHg in both eyes with no antiglaucoma medication. He had one episode of mild iritis in both eyes, but there was no spike of IOP.

**Patient 7**

This Chinese man was first seen in April 1989 at the age of 36, with misty vision of the right eye, headache, and ocular discomfort. His vision was 6/6 in both eyes. There was mild epithelial edema of the cornea with a few keratic precipitates and cells seen on slit-lamp examination of the right eye. The IOP was 36 mmHg. Gonioscopy showed open angle. The left eye was normal. He had nine episodes of PSS crises over the next 6 years, with a highest IOP of 44 mmHg. In 1995 his cup/disc ratio was noted to be 0.6 in the right eye and 0.3 in the left eye. Visual fields in January 1996 showed a superior arcuate defect (Fig 2A). He had another three attacks after that, and in December 1997 the field loss in the right eye had progressed to a dense superior hemifield defect (Fig 2B). He underwent a trabeculectomy with mitomycin-C in January 1998, and the IOP has been less than 18 mmHg on no medications. He has had one attack since, with no elevation in IOP.

**Discussion**

One fourth of the eyes in our series of PSS patients had glaucomatous damage. None of these eyes had evidence of coexisting POAG. The major determinant of occurrence of glaucoma was the duration of the disease. Because this is a retrospective study, it was not possible to accurately determine the duration of elevated IOP during each episode and the number of attacks that the patients had had. Although these patients were followed up at 6 month intervals and asked to return earlier if they had an attack, some of the patients may not have sought treatment for every attack, because they were short-lived. Hence, we could not conclusively exclude the possibility that the duration of the attack and number of attacks were also factors in causing glaucoma in these patients.

Although these patients were from the Uveitis Clinic, they constitute more than 90% of all PSS patients seen at the Singapore National Eye Centre and therefore are fairly representative of the group.

Our longitudinal study shows that PSS in our population is not as benign as was previously thought. This was also observed in another study, which again involved a predominantly Chinese population. Although this has not been described so far among PSS patients of other races, we recommend that all patients with PSS need to be carefully examined for evidence of glaucoma even in the absence of associated POAG.

This study also shows that glaucoma filtering surgery with antimetabolites is successful in preventing IOP spikes during the cyclitic attacks in most cases (80%). There also seems to be a reduction in the number of attacks that these individuals have after surgery. This decrease in the severity of the uveitis has also been noted by others, and we suggest that it is possible that a functioning filtering bleb may allow egress of inflammatory cells from the eye, and this may in turn protect the bleb from failure. This would be in keeping with the observation by Hill et al that in patients with chronic uveitis who had received Molteno

| Table 3. Factors in Development of Glaucoma in Patients with Posner Schlossman Syndrome |
|-----------------|-----------|-----------|------|
| Factor          | Glaucoma  | No Glaucoma | P    |
| Mean age at onset (yrs) | 38        | 34        | ns   |
| Mean duration of disease (yrs) | 10        | 5         | 0.04 |
| Mean highest IOP (mmHg)       | 49        | 46        | ns   |
| Mean number of attacks        | 9         | 8         | ns   |

IOP = intraocular pressure; ns = not statistically significant at 95% level.
Figure 1. A, Automated perimetry of the right eye of a patient with Posner Schlossman syndrome showing superior arcuate and inferior nasal field loss. B, Automated perimetry of the left eye of the same patient showing a nasal field defect. C, Automated perimetry of the right eye 4 years later showing no further change in field defects. D, Automated perimetry of the left eye 10 months (January 1996) after trabeculectomy, showing extensive superior and inferior arcuate losses. E, Automated perimetry of the left eye 5 months (March 2000) after cataract surgery, showing superior and inferior arcuate losses.
Figure 2. A, Automated perimetry of the right eye of a patient with Posner Schlossman syndrome showing a superior arcuate field defect. B, Automated perimetry of the same eye 2 years later showing worsening of field loss with a dense superior hemifield defect.
implants, the drainage tubes removed the inflammatory cells from the anterior chamber. However, again in a retrospective study, there may have been missed episodes, because these patients may now have less severe symptoms and therefore not seek treatment.

Furthermore, glaucoma surgery should be advised as soon as glaucoma change has occurred, because the rate of progression can be quite rapid in these individuals.
